INTRODUCTION: *Euphoria sepulcralis* (Fabricius) is a common, day-flying scarab in Florida and much of the eastern half of the United States, and one of the beetles most frequently submitted to the Entomology Section for identification. Occasionally, it achieves pest status because of the damage it does to corn, roses, and the flowers of blooming fruit trees.

IDENTIFICATION: This species is one of seven in four genera of the scarab subfamily Cetoniinae known from Florida in which the mesepimera are visible from above between the pronotum and elytral humeri (Fig. 1) and the mandibles are small and mostly membranous. Of these, only *E. sepulcralis* and *Protaetia fusca* (Herbst) are dark with white or cream markings. *Euphoria sepulcralis* is 10mm - 14mm long, dark brown to black, with metallic bronze or green reflections. Dorsally, it is heavily punctate, with the surface between punctures smooth and shining. The elytra are slightly dentate at the sutural angle and are ornamented with white cretaceous spots, arranged more or less transversely. *Protaetia fusca* is an Asian species established in southeastern Florida. It is sparsely punctate with the surface between punctures dull, the cretaceous spots are present on the elytra and pronotum, and the sutural angle is usually strongly spinose. Although the spelling *sepulchralis* occurs in nearly all literature, Ratcliffe (1991) noted that the spelling in the original description (Fabricius 1801) is *sepulcralis*. Casey (1915) described a number of subspecies, which are not considered here.

BIOLOGY: Little is known about the biology of this species, especially of the immature stages. Larvae have been found in soil beneath dead sod or manure (Ritcher 1945). The length of the larval stage averaged 62.7 days and of the pupal stage 15.4 days (Hayes 1925). Pupation is in an earthen cell (Ratcliff 1991). In Kentucky, Ritcher (1945) reported the beetles have a one-year life cycle with pupation occurring in August and adults flying from August to October and again in the spring. In Florida, adults have been collected in all months except October and December, with peak summer abundance in August, at least in Alachua County (Landolt 1990). Adults are found on flowers, where they apparently are pollen feeders, at fermenting sap flows (Fig. 2), and on ripe or decaying fruit. Landolt (1990) found that adults are attracted to isopropyl (rubbing) alcohol and Cherry and Klein (1992) showed they are attracted to various aromatic compounds used in Japanese beetle (*Popillia japonica* Newman) traps.

HOSTS: Ratcliffe (1991) noted: "The adults feed on tree sap, a wide variety of ripening fruits, corn, and the flowers of apple, thistle, mock orange, milkweed, dogwood, sumac, yarrow, daisies, and goldenrod." Plant associations from DPI records and FSCA specimens are: *Acalypha* sp., *Acer rubrum* L. (foliage), *Adonidia* sp., *Alcea rosea* L., *Allamanda* sp., *Ambrosia artemisiifolia* L., *Ambrosia* sp., *Anethum* sp., *Aronia arbutifolia* (L.) Pers., *Asimina reticulata* Chapm., *Asimina triloba* (L.) Dunal, *Asystasia gangetica* (L.) T. Anders., *Averrhoa carambola* L., *Baccharis angustifolia* Michx., *Bidens bipinnata* L., *Bidens* sp., *Bombax* sp., *Borreria* sp., *Brassica juncea* (L.) Czerniak, *Brassica oleracea* L., *Bucida buceras* L., *Bursera simaruba* (L.) Sarg., *Callistemon viminalis* (Sol. ex Gaertn.) G. Don ex

DISTRIBUTION: *Euphoria sepulchralis* is found throughout the eastern U.S. as far north as Illinois and Indiana and west to Texas (Ritcher 1945; Ratcliffe 1991). There are also specimens in the Florida State Collection of Arthropods from Nassau, Bahamas. It occurs everywhere in Florida, from Escambia County in the western Panhandle to Key West in Monroe County. DPI records and FSCA specimens represent 189 localities in 52 of Florida's 67 counties.

PEST STATUS: *Euphoria sepulchralis* has been recorded as a pest of corn (Ritcher 1945; Ratcliffe 1991) and roses (Spencer and Jarratt 1989). DPI records for Florida include many for those hosts, with annotations such as "10-15 beetles per ear of corn." Records also suggest it can be a pest of mango and avocado in South Florida, where large numbers of the beetles destroy the flowers and thus reduce the number of fruits produced. There are also records of the beetles invading bee hives and damaging combs.

ACKNOWLEDGEMENTS: I thank Brenda Beck for helping to compile locality and host records, and DPI botanist Dr. Nancy Coile for checking plant names.
